

(See <https://cs.stanford.edu/~knuth/programs.html> for date.)

1. Intro. This is an experimental program to find “rooted” graceful labelings of a given graph. (Some of the vertex labels may be prespecified. Every edge has a vertex in common with a longer edge, or has at least one prespecified vertex, except possibly for edge m itself.)

I hacked this code from BACK-GRACEFUL-ROOTED, which considered the special case where vertex 0 (only) was prespecified, and which looked exhaustively for *all* solutions. By contrast, this program is intended for large graphs, where we feel lucky to find even a single solution and we can’t hope to find them all. Therefore we’ll use randomization with frequent restarts.

(Thanks to Tom Rokicki for many of the ideas used here.)

```
#define maxn 64    /* at most this many vertices */
#define maxm 128   /* at most this many edges */
#define interval 100 /* print ‘.’ to show progress, every so often */

#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include "gb_graph.h"
#include "gb_save.h"
#include "gb_flip.h"
  (Global variables 5);

main(int argc, char *argv[])
{
  register int i, j, k, l, m, n, p, q, r, t, bad, vv, ll;
  Graph *g;
  Vertex *v, *w;
  Arc *a;

  (Process the command line, and set prespec to the prespecified labelings 2);
  (Set up the fixed data structures 3);
  while (1) {
    rounds++;
    if ((rounds % interval) == 0) fprintf(stderr, ".");
    (Set the cutoff for a new trial 4);
    (Backtrack for at most  $T$  steps 8);
  }
}
```

2. The command line names a graph in SGB format, followed by a minimum cutoff time T_{\min} (measured in search tree nodes examined before restarting). Then comes a random seed, so that results of this run can be replicated if necessary. Then come zero or more prespecifications, in the form ‘VERTNAME=label’.

```

⟨ Process the command line, and set prespec to the prespecified labelings 2 ⟩ ≡
  if (argc < 4 ∨ sscanf(argv[2], "%lld", &Tmin) ≠ 1 ∨ sscanf(argv[3], "%d", &seed) ≠ 1) {
    fprintf(stderr, "Usage: %sfoo.gbTminseed[VERTEX=label...]\n", argv[0]);
    exit(-1);
  }
  g = restore_graph(argv[1]);
  if (¬g) {
    fprintf(stderr, "I couldn't reconstruct graph %s!\n", argv[1]);
    exit(-2);
  }
  m = g-m/2, n = g-n;
  if (m > maxm) {
    fprintf(stderr, "Sorry, at present I require m ≤ %d!\n", maxm);
    exit(-3);
  }
  if (n > maxn) {
    fprintf(stderr, "Sorry, at present I require n ≤ %d!\n", maxn);
    exit(-4);
  }
  for (k = 4; argv[k]; k++) {
    for (i = 1; argv[k][i]; i++)
      if (argv[k][i] ≡ '=') break;
    if (¬argv[k][i] ∨ sscanf(&argv[k][i+1], "%d", &label) ≠ 1 ∨ label < 0 ∨ label > m) {
      fprintf(stderr, "spec '%s' doesn't have the form 'VERTEX=label'!\n", argv[k]);
      exit(-3);
    }
    argv[k][i] = 0;
    for (j = 0; j < n; j++)
      if (strcmp((g-vertices + j)-name, argv[k]) ≡ 0) break;
    if (j ≡ n) {
      fprintf(stderr, "There's no vertex named '%s'!\n", argv[k]);
      exit(-5);
    }
    if (verttoprespec[j]) {
      fprintf(stderr, "Vertex %s was already specified!\n", (g-vertices + j)-name);
      exit(-6);
    }
    verttoprespec[j] = 1;
    if (¬xprespec ∧ (label ≡ 0 ∨ label ≡ m)) xprespec = 1, prespec[0] = (j ≪ 8) + label;
    else prespec[prespecptr++] = (j ≪ 8) + label;
  }
  gb_init_rand(seed);
  fprintf(stderr, "OK, I've got a graph with %d vertices, %d edges.\n", n, m);

```

This code is used in section 1.

3. \langle Set up the fixed data structures 3 $\rangle \equiv$
for ($k = 0$; $k < n$; $k++$) {
 $v = g\text{-vertices} + k$;
 for ($a = v\text{-arcs}$; a ; $a = a\text{-next}$) {
 $w = a\text{-tip}$;
 $edges[k][deg[k]++] = w - g\text{-vertices}$;
 }
 }
for ($k = 0$; $k < prespecptr$; $k++$) $moves[k] = 1, move[k][0] = prespec[k]$;

This code is used in section 1.

4. Las Vegas algorithms like this one are best controlled by multiples of the “reluctant doubling” sequence defined by Luby, Sinclair, and Zuckerman (see equation 7.2.2.2–(131) in *TAOCP*), unless we already know a pretty good cutoff value.

\langle Set the cutoff for a new trial 4 $\rangle \equiv$
 $T = Tmin * reluctant_v$;
if ($(reluctant_u \ \& \ -reluctant_u) \neq reluctant_v$) $reluctant_v \ll= 1$;
else $reluctant_u++$, $reluctant_v = 1$;

This code is used in section 1.

5. \langle Global variables 5 $\rangle \equiv$
int $vbose = 0$; /* set this nonzero to watch me work */
int $rounds$; /* how many random trials have we started? */
long long $nodes$; /* how many nodes have we started on this round? */
long long $reluctant_u = 1, reluctant_v = 1$; /* restart parameters */
long long T ; /* cutoff time for the current random trial */
long long $Tmin$; /* minimum cutoff time (from the command line) */
int $seed$; /* seed for gb_init_rand */
int $label$; /* a label value read from $argv[k]$ */
int $prespec[maxn]$; /* prespecified labels */
int $verrtoprespec[maxn]$; /* has this vertex been prespecified? */
int $prespecptr = 1$; /* how many are prespecified? */
int $xprespec$; /* did any of them specify label 0 or label m ? */

See also sections 6 and 17.

This code is used in section 1.

6. Data structures. The vertices are internally numbered from 0 to $n-1$. Vertex v has $\text{deg}[v]$ neighbors, and they appear in the first $\text{deg}[v]$ slots of $\text{edges}[v]$. Its label is $\text{verttolab}[v]$; but $\text{verttolab}[v] = -1$ if v hasn't yet been labeled.

Labels potentially range from 0 to m . If label l hasn't yet been used, $\text{labunlab}[l]$ is negative, and $\text{labtovert}[l]$ is undefined. Otherwise $\text{labtovert}[l]$ is the vertex labeled l , and $\text{labunlab}[l]$ is the number of unlabeled neighbors of that vertex.

For each q between 1 and m , $\text{edgcount}[q]$ is the number of edges labeled q . (This number might momentarily exceed 1, although it will be exactly equal to 1 when the labeling is graceful.)

⟨ Global variables 5 ⟩ \equiv

```

int  $\text{deg}[\text{maxn}]$ ;      /* how many neighbors of  $v$ ? */
int  $\text{edges}[\text{maxn}][\text{maxm}]$ ; /* their identities */
int  $\text{verttolab}[\text{maxn}]$ ; /* what is  $v$ 's label? */
int  $\text{labtovert}[\text{maxm} + 1]$ ; /* what vertex  $v[l]$  is labeled  $l$ ? */
int  $\text{labunlab}[\text{maxm} + 1]$ ; /* how many unlabeled neighbors does  $v[l]$  have? */
int  $\text{edgcount}[\text{maxm} + 1]$ ; /* how many edges are labeled  $q$ ? */

```

7. We begin by converting from Stanford GraphBase format to the data structures used here.

⟨ Initialize the data structures 7 ⟩ \equiv

```

for ( $k = 0$ ;  $k < n$ ;  $k++$ ) {
     $\text{verttolab}[k] = -1$ ;
}
for ( $q = 0$ ;  $q \leq m$ ;  $q++$ )  $\text{labunlab}[q] = -1$ ,  $\text{edgcount}[q] = 0$ ;

```

This code is used in section 8.

8. Backtracking. The main computation is based on Walker's backtrack method, Algorithm 7.2.2W. It's an implicit recursion, spelled out so that the costs of updating and downdating are made explicit.

```

⟨ Backtrack for at most  $T$  steps 8 ⟩ ≡
w1: ⟨ Initialize the data structures 7 ⟩;
     $l = 0, nodes = 0$ ;
    if ( $\neg xprespec$ ) {
        while (1) {
             $vv = (n * (\text{unsigned long long}) gb\_next\_rand()) \gg 31$ ;
            if ( $\neg verttoprespec[vv]$ ) break;
        }
         $move[0][0] = vv \ll 8$ ;
    }
w2: if ( $++nodes > T$ ) goto done;
    if ( $l < prespecptr$ ) {
         $r = 1$ ;
        goto w3;
    }
     $q = target[l - 1]$ ;
    for ( $q = (q ? q - 1 : m)$ ;  $edgecount[q]$ ;  $q--$ ) ;
    if ( $q \equiv 0$ ) ⟨ Visit a solution and goto done 10 ⟩;
     $target[l] = q$ ;
    ⟨ Determine the  $r$  potential moves that might create edge  $q$  12 ⟩;
    ⟨ Shuffle those moves 11 ⟩;
     $moves[l] = r$ ;
w3: if ( $r > 0$ ) {
     $t = move[l][--r]$ ;
     $vv = t \gg 8, ll = t \& \#ff$ ;
    if ( $vbose$ ) ⟨ Show this potential move 9 ⟩;
    ⟨ Update the edge counts that would result from  $verttolab[vv] = ll$ , setting  $bad$  nonzero if any of them
      would exceed 1, also setting  $p$  to the number of unlabeled neighbors of  $vv$  13 ⟩;
    if ( $bad$ ) goto w4a;
    ⟨ Give label  $ll$  to vertex  $vv$  15 ⟩;
     $x[l++] = r$ ;
    goto w2;
}
w4: if ( $--l \geq 0$ ) {
     $r = x[l], t = move[l][r], vv = t \gg 8, ll = t \& \#ff$ ;
    ⟨ Take label  $ll$  from vertex  $vv$  16 ⟩;
w4a: ⟨ Downdate the edge counts that would result from  $verttolab[vv] = ll$  14 ⟩;
    goto w3;
}
done:

```

This code is used in section 1.

```

9. ⟨ Show this potential move 9 ⟩ ≡
if ( $target[l]$ )  $fprintf(stderr, "L\%d:\%s=\%d\ (%d\ of\ %d\ for\ edge\ %d)\n", l, (g-vertices + vv)-name, ll,$ 
     $moves[l] - r, moves[l], target[l]);$ 
else  $fprintf(stderr, "L\%d:\%s=\%d\ (prespecified)\n", l, (g-vertices + vv)-name, ll);$ 

```

This code is used in section 8.

10. $\langle \text{Visit a solution and goto done 10} \rangle \equiv$

```

{
    count++;
    fprintf(stderr, "\n");
    for (k = 0; k ≤ m; k++)
        if (labunlab[k] ≥ 0) {
            if (labunlab[k] > 0) fprintf(stderr, "This can't happen!\n");
            vv = labtovert[k];
            printf("%s=%d", (g→vertices + vv)→name, k);
        }
    printf("#%d (round %d, step %lld\n", count, rounds, nodes);
    fflush(stdout);
    goto done;
}

```

This code is used in section 8.

11. By giving an arbitrary permutation to the list of possible moves, we're providing the maximum randomization over the entire search tree for all rooted labelings that meet the prespecifications.

I don't think this will add a significant amount to the running time. But if it does, we could back off by doing only a partial shuffle (for example, only on certain levels, or a maximum of 10 swaps, or ...).

$\langle \text{Shuffle those moves 11} \rangle \equiv$

```

for (q = r - 1; q > 0; q--) {
    p = ((q + 1) * ((unsigned long long) gb_next_rand())) >> 31;
    t = move[l][p];
    move[l][p] = move[l][q];
    move[l][q] = t;
}

```

This code is used in section 8.

12. I think this is the inner loop.

$\langle \text{Determine the } r \text{ potential moves that might create edge } q \text{ 12} \rangle \equiv$

```

for (r = j = 0, k = q; k ≤ m; j++, k++) {
    if (labunlab[j] > 0 ∧ labunlab[k] < 0) {
        for (vv = labtovert[j], i = deg[vv] - 1; i ≥ 0; i--) {
            t = verttolab[edges[vv][i]];
            if (t < 0) move[l][r++] = (edges[vv][i] << 8) + k;
        }
    } else if (labunlab[j] < 0 ∧ labunlab[k] > 0) {
        for (vv = labtovert[k], i = deg[vv] - 1; i ≥ 0; i--) {
            t = verttolab[edges[vv][i]];
            if (t < 0) move[l][r++] = (edges[vv][i] << 8) + j;
        }
    }
}
}

```

This code is used in section 8.

13. And this loop too is pretty much “inner.”

⟨ Update the edge counts that would result from $verttolab[vv] = ll$, setting bad nonzero if any of them would exceed 1, also setting p to the number of unlabeled neighbors of vv 13 ⟩ \equiv

```

for ( $p = deg[vv], i = p - 1, bad = 0; i \geq 0; i--$ ) {
     $t = verttolab[edges[vv][i]];$ 
    if ( $t \geq 0$ ) {
         $p--;$ 
         $q = abs(t - ll);$ 
         $t = edgecount[q], bad |= t;$ 
         $edgecount[q] = t + 1;$ 
    }
}

```

This code is used in section 8.

14. Maybe the last line here will go faster if rewritten ‘ $edgecount[abs(t - ll)] -= (t \geq 0)$ ’, because of branch prediction? If so, are modern compilers smart enough to see this?

⟨ Downdate the edge counts that would result from $verttolab[vv] = ll$ 14 ⟩ \equiv

```

for ( $i = deg[vv] - 1; i \geq 0; i--$ ) {
     $t = verttolab[edges[vv][i]];$ 
    if ( $t \geq 0$ )  $edgecount[abs(t - ll)]--;$ 
}

```

This code is used in section 8.

15. The value of p has been set up for us nicely at this point.

We need to perform another loop, but this one isn’t needed quite so often.

⟨ Give label ll to vertex vv 15 ⟩ \equiv

```

 $verttolab[vv] = ll, labtovert[ll] = vv, labunlab[ll] = p;$ 
for ( $i = deg[vv] - 1; i \geq 0; i--$ ) {
     $t = verttolab[edges[vv][i]];$ 
    if ( $t \geq 0$ )  $labunlab[t]--;$ 
}

```

This code is used in section 8.

16. ⟨ Take label ll from vertex vv 16 ⟩ \equiv

```

for ( $i = deg[vv] - 1; i \geq 0; i--$ ) {
     $t = verttolab[edges[vv][i]];$ 
    if ( $t \geq 0$ )  $labunlab[t]++;$ 
}
 $verttolab[vv] = labunlab[ll] = -1;$ 

```

This code is used in section 8.

17. ⟨ Global variables 5 ⟩ $+=$

```

int  $count;$  /* this many solutions found so far */
int  $target[maxn];$  /* the edge we try to set, on each level */
int  $move[maxn][maxm];$  /* the things we want to try, on each level */
int  $x[maxn];$  /* the moves currently being tried, on each level */
int  $moves[maxn];$  /* used in verbose tracing only */

```
