1. Intro. Serhiy Grabarchuk noticed that that are ten ways to glue a small domino over a large domino, where the sides of the large domino are $\sqrt{2}$ times as long as the sides of the small one, and the small domino is at a 45° angle with respect to the large one. (This means that the two grids line up nicely.) This program generates DLX data to pack those ten pieces into an $m \times n$ box—meaning a rectangular box that could hold mn/2 large dominoes, if there were no small ones. (Such a box could also hold mn-m-n small dominoes, tilted, if there were no large ones.)

Let's use Cartesian coordinates instead of matrix-like coordinates. Imagine that the grid for large dominoes is bounded by the lines x = 0, x = 2n, y = 0, and y = 2m. Represent each large square by its midpoint. Thus the mn large squares are (x, y) for 0 < x < 2n and 0 < y < 2m, where x and y are odd.

The center of every large square is a corner point of four small squares. And the center point of every small square is (x, y) where x + y is odd. That makes n(m - 1) cases with x odd, and (n - 1)m cases with x even.

The pieces are numbered 0 to 9, somewhat arbitrarily.

This program simply packs the pieces without overlapping. With change files I can add other constraints.

```
#include <stdio.h>
#include <stdlib.h>
