§1 SIMPATH-HAM-ANY INTRODUCTION 1

(Downloaded from https://cs.stanford.edu/~knuth/programs.html and typeset on May 28, 2023)

1.* Introduction. This program inputs an undirected graph and the names of two vertices in that graph (the "source" and "target" vertices). It outputs a not-necessarily-reduced binary decision diagram for the family of all simple paths from the source to the target.

The format of the output is described in another program, SIMPATH-REDUCE. Let me just say here that it is intended only for computational convenience, not for human readability.

I've tried to make this program simple, whenever I had to choose between simplicity and efficiency. But I haven't gone out of my way to be inefficient.

```
/* maximum number of vertices; at most 254 */
#define maxn 254
                                 /* code for a dummy vertex adjacent to all */
#define dummy maxn + 1
#define maxm 2000
                          /* maximum number of edges */
#define logmemsize 27
#define memsize (1 \ll logmemsize)
#define loghtsize 25
#define htsize \ (1 \ll loghtsize)

     fprintf(stderr, "I_{\sqcup}can't_{\sqcup}find_{\sqcup}target_{\sqcup}vertex_{\sqcup}%s_{\sqcup}in_{\sqcup}the_{\sqcup}graph! \n", argv[3]);
      exit(-7);
This code is used in section 1*.
```

§3 SIMPATH-HAM-ANY INTRODUCTION

3. If the source vertex is the first vertex in the graph, I'll process vertices according to the graph's own ordering.

Otherwise, I use a simple breadth-first strategy to number the vertices: The source is vertex 1. Then, for each $j \ge 1$, I run through the arcs from vertex j and assign the first unused number to any of its neighbors that haven't already got one.

```
\#define num \ z.I
\langle \text{ Renumber the vertices } 3 \rangle \equiv
  if (source \equiv g \rightarrow vertices) {
     for (k = 0; k < n; k++) (g \rightarrow vertices + k) \rightarrow num = k+1, vert[k+1] = g \rightarrow vertices + k;
   } else {
     for (k = 0; k < n; k++) (g \rightarrow vertices + k) \rightarrow num = 0;
     vert[1] = source, source \neg num = 1;
     for (j = 0, k = 1; j < k; j ++) {
        v = vert[j+1];
        for (a = v \rightarrow arcs; a; a = a \rightarrow next) {
           u = a \rightarrow tip;
           if (u \rightarrow num \equiv 0) u \rightarrow num = ++k, vert[k] = u;
     if (target \neg num \equiv 0) {
        fprintf(stderr, "Sorry, \_there's \_no \_path \_from \_%s \_to \_%s \_in \_the \_graph! \n", argv[2], argv[3]);
        exit(-8);
     if (k < n) {
        fprintf(stderr, "The \_graph \_ isn't \_connected \_ (%d<%d)! \n", k, n);
        fprintf(stderr, "But_that's_0K;_UI'll_work_with_the_component_of_%s.\n", argv[2]);
        n=k;
  }
```

This code is used in section 1^* .

4 INTRODUCTION SIMPATH-HAM-ANY §4

4.* The edges will be considered as arcs $j \to k$ between vertex number j and vertex number k, when j < k and those vertices are adjacent in the graph. We process them in order of increasing j; but for fixed j, the values of k aren't necessarily increasing.

The k values appear in the arcto array. The edges for fixed j occur in positions firstarc[j] through firstarc[j+1]-1 of that array.

After this step, we forget the GraphBase data structures and just work with our homegrown integer-only representation.

```
\langle \text{ Reformat the edges } 4^* \rangle \equiv
   for (m = 0, k = 1; k \le n; k++) {
       firstarc[k] = m;
       v = vert[k];
       printf("%ld(%s)\n", v \rightarrow num, v \rightarrow name);
       for (a = v \rightarrow arcs; a; a = a \rightarrow next) {
          u = a \rightarrow tip;
          if (u \rightarrow num > k) {
              arcto[m++] = u \rightarrow num;
              if (a \rightarrow len \equiv 1) printf("\square \rightarrow \square \text{ld}(\text{s}) \square \text{#}\text{ld} \text{n}", u \rightarrow num, u \rightarrow name, m);
              else printf(" \_ -> \_ \% ld(\%s, \% ld) \_ \# \% d n", u \rightarrow num, u \rightarrow name, a \rightarrow len, m);
          }
       arcto[m++] = dummy;
       printf(" \_ -> \_ dummy, 0 \_ #%d \n", m);
   firstarc[k] = m;
This code is used in section 1^*.
```

§5 SIMPATH-HAM-ANY THE ALGORITHM

5. The algorithm. Now comes the fun part. We systematically construct a binary decision diagram for all simple paths by working top-down, considering the arcs in *arcto*, one by one.

When we're dealing with arc i, we've already constructed a table of all possible states that might arise when each of the previous arcs has been chosen-or-not, except for states that obviously cannot be part of a simple path.

Arc i runs from vertex j to vertex k = arcto[i]. Let l be the maximum vertex number in arcs less than i. (If the breadth-first ordering option was taken above, we'll always have $k \le l+1$, because of the way we did the numbering and reformatting; but that method is not always best.)

The state before we decide whether or not to include arc i is represented by a table of values mate[t], for $j \leq t \leq l$, with the following significance: If mate[t] = t, the previous arcs haven't touched vertex t. If mate[t] = u and $u \neq t$, the previous arcs have connected t with u by a simple path. If mate[t] = 0, the previous arcs have "saturated" vertex t; we can't touch it again.

We also use a (slick?) trick: We imagine that an edge between the source and target has already been included. Then the final arc of a simple path will be an arc that completes a cycle, when no other incomplete paths are present. (Think about it.)

The *mate* information is all that we need to know about the behavior of previous arcs. And it's easily updated when we add the *i*th arc (or not). So each "state" is equivalent to a *mate* table, consisting of l+1-j numbers.

The states are stored in a queue, indexed by 64-bit numbers tail, boundary, and head, where $tail \le boundary \le head$. Between tail and boundary are the pre-arc-i states that haven't yet been processed; between boundary and head are the post-arc-i states that will be considered later. The states before boundary are sequences of s = l + 1 - j bytes each, and the states after boundary are sequences of s = l + 1 - jj bytes each, where ll and jj are the values of l and j for arc i + 1.

Bytes of the queue are stored in mem, which wraps around modulo memsize. We ensure that head-tail never exceeds memsize.

```
\langle \text{ Do the algorithm 5} \rangle \equiv
   \langle \text{ Initialize the } mate \text{ table } 6^* \rangle;
   \langle \text{Initialize the queue } 7 \rangle;
   for (i = 0; i < m; i ++) {
     printf("#%d: \n", i + 1);
                                          /* announce that we're beginning a new arc */
     fprintf(stderr, "Beginning_arc_\%d_(serial=\%d,head-tail=\%lld)\n", i+1, serial, head-tail);
     fflush(stderr);
     \langle \text{Process arc } i \text{ 8*} \rangle;
This code is used in section 1*.
6.* \langle Initialize the mate table 6.* \rangle \equiv
  for (t = 2; t < n; t++) mate[t] = t;
   mate[dummy] = 1, mate[1] = dummy;
This code is used in section 5.
7. \langle \text{Initialize the queue 7} \rangle \equiv
  jj = ll = 1;
   mem[0] = mate[1];
   tail = 0, head = 1;
   serial = 2;
This code is used in section 5.
```

6 THE ALGORITHM SIMPATH-HAM-ANY §8

8.* Each state for a particular arc gets a distinguishing number. Two states are special: 0 means the losing state, when a simple path is impossible; 1 means the winning state, when a simple path has been completed. The other states are 2 or more.

The output format on stdout simply shows the identifying numbers of a state and its two successors, in hexadecimal.

```
#define trunc(addr) ((addr) & (memsize - 1))
\langle \text{ Process arc } i \text{ 8*} \rangle \equiv
  boundary = head, htcount = 0, htid = (i + wrap) \ll logmemsize;
  if (htid \equiv 0) {
     for (hash = 0; hash < htsize; hash ++) htable[hash] = 0;
     wrap +++, htid = 1 \ll logmemsize;
  newserial = serial + ((head - tail)/(ll + 1 - jj));
  j = jj, k = arcto[i], l = ll;
  while (jj \le n \land firstarc[jj+1] \equiv i+1) \ jj++;
  ll = (k \equiv dummy ? l: k > l? k: l);
  while (tail < boundary) {
     printf("\%x:", serial);
     serial ++;
     \langle \text{Unpack a state, and move } tail \text{ up } 9^* \rangle;
     \langle \text{Print the successor if arc } i \text{ is not chosen } 11 \rangle;
     printf(",");
     \langle \text{ Print the successor if arc } i \text{ is chosen } 10 \rangle;
     printf("\n");
This code is used in section 5.
9. If the target vertex hasn't entered the action yet (that is, if it exceeds l), we must update its mate entry
at this point.
\langle \text{Unpack a state, and move } tail \text{ up } 9^* \rangle \equiv
  mate[dummy] = 0;
  for (t = j; t \le l; t++, tail++) {
     mate[t] = mem[trunc(tail)];
     if (mate[t] \equiv dummy) mate[dummy] = t;
This code is used in section 8*.
10. Here's where we update the mates. The order of doing this is carefully chosen so that it works fine
when mate[j] = j and/or mate[k] = k.
\langle \text{Print the successor if arc } i \text{ is chosen } 10 \rangle \equiv
  jm = mate[j], km = mate[k];
  if (jm \equiv 0 \lor km \equiv 0) printf("0");
                                                /* we mustn't touch a saturated vertex */
  else if (jm \equiv k) (Print 1 or 0, depending on whether this arc wins or loses 12^*)
  else {
     mate[j] = 0, mate[k] = 0;
     mate[jm] = km, mate[km] = jm;
     printstate(j, jj, ll);
     mate[jm] = j, mate[km] = k, mate[j] = jm, mate[k] = km;
                                                                            /* restore original state */
```

This code is used in section 8^* .

done:

§11 SIMPATH-HAM-ANY THE ALGORITHM

```
11. \langle \text{Print the successor if arc } i \text{ is not chosen } 11 \rangle \equiv printstate(j, jj, ll);
This code is used in section 8*.
```

12* See the note below regarding a change that will restrict consideration to Hamiltonian paths. A similar change is needed here.

```
 \langle \operatorname{Print} 1 \text{ or } 0, \operatorname{depending on whether this arc wins or loses } 12^* \rangle \equiv \\ \{ \\ \operatorname{for } (t = j + 1; \ t \leq ll; \ t + +) \\ \operatorname{if } (t \neq k) \ \{ \\ \operatorname{if } (mate[t]) \ \operatorname{break}; \\ \} \\ \operatorname{if } (t > n) \ \operatorname{printf}("1"); \ /* \ \text{we win: this cycle is all by itself } */ \\ \operatorname{else} \ \operatorname{printf}("0"); \ /* \ \text{we lose: there's junk outside this cycle } */ \\ \} \\ \operatorname{This code is used in section } 10.
```

13* The *printstate* subroutine does the rest of the work. It makes sure that no incomplete paths linger in positions j through jj - 1, which are about to disappear; and it puts the contents of mate[jj] through mate[ll] into the queue, checking to see if it was already there.

If 'mate $[t] \neq t$ ' is removed from the condition below, we get Hamiltonian paths only (I mean, simple paths that include every vertex).

```
\langle \text{Subroutines } 13^* \rangle \equiv
  void printstate(int j, int jj, int ll)
    register int h, hh, ss, t, tt, hash;
    for (t = j; t < jj; t++)
       if (mate[t]) break;
    if (t < jj) printf("0");
                               /* incomplete junk mustn't be left hanging */
    else if (ll < jj) printf("0"); /* nothing is viable */
    else {
       ss = ll + 1 - jj;
       if (head + ss - tail > memsize) {
         fprintf(stderr, "Oops, LI'm_out_lof_memory_l(memsize=%d, Lserial=%d)! \n", memsize, serial);
         fflush(stdout);
         exit(-69);
       \langle Move the current state into position after head, and compute hash 14\rangle;
       \langle Find the first match, hh, for the current state after boundary 15\rangle;
       h = trunc(hh - boundary)/ss;
       printf("%x", newserial + h);
This code is used in section 1*.
14. (Move the current state into position after head, and compute hash 14) \equiv
  for (t = jj, h = trunc(head), hash = 0; t \le ll; t++, h = trunc(h+1)) {
    mem[h] = mate[t];
    hash = hash * 31415926525 + mate[t];
```

This code is used in section 13*.

8 THE ALGORITHM SIMPATH-HAM-ANY §15

15. The hash table is automatically cleared whenever *htid* is increased, because we store *htid* with each relevant table entry.

```
\langle Find the first match, hh, for the current state after boundary 15\rangle \equiv
  for (hash = hash \& (htsize - 1); ; hash = (hash + 1) \& (htsize - 1)) {
     hh = htable[hash];
     if ((hh \oplus htid) \ge memsize) (Insert new entry and goto found 16);
     hh = trunc(hh);
     for (t = hh, h = trunc(head), tt = trunc(t + ss - 1); ; t = trunc(t + 1), h = trunc(h + 1))
       if (mem[t] \neq mem[h]) break;
       if (t \equiv tt) goto found;
  found:
This code is used in section 13*.
16. \langle Insert new entry and goto found | 16\rangle \equiv
  {
     if (++htcount > (htsize \gg 1)) {
       fprintf(stderr, "Sorry, \bot the \bot hash \bot table \bot is \bot full \bot (htsize=%d, \bot serial=%d)! \n", htsize, serial);
       exit(-96);
     hh = trunc(head);
     htable[hash] = htid + hh;
     head += ss;
     goto found;
This code is used in section 15.
```
