§1

1. Intro. Given a graph q with m edges, make data from which DLX2 should tell us all ways to label the vertices, using distinct labels in  $\{0, 1, \dots, m\}$ , so that the edges have distinct difference. (Those differences will be  $\{1, ..., m\}$ .

Selected vertex labels may be prespecified on the command line, as in BACK-GRACEFUL.

```
#define encode(x) ((x) < 10? (x) + '0': (x) < 36? (x) - 10 + 'a': (x) < 62? (x) - 36 + 'A': (x) + 99)
                        /* based on that encoding, but I could go higher in a pinch! */
#define maxm 156
\#define maxn 100
#include <stdio.h>
#include <stdlib.h>
#include "gb_graph.h"
#include "gb_save.h"
  int c;
  int label;
               /* a label value read from argv[k] */
  int prespec[maxn]; /* prespecified labels */
  int verttoprespec[maxn]; /* has this vertex been prespecified? */
                    /* how many are prespecified? */
  int prespecttr;
  main(\mathbf{int} \ argc, \mathbf{char} * argv[])
    register int i, j, k, m, n, p, x, bad;
    register Arc *a;
    register Graph *q;
    register Vertex *v, *w;
    (Process the command line, and set prespec to the prespecified labelings 2);
    (Output the item-name line 3);
    for (k = 1; k \le m; k++) (Output the options for edge k \ne 4);
```

ξ2

```

      printf("\n");
This code is used in section 1.
```

3

**3.** There's a primary item k for each edge label, and a primary item uv for each edge. This enforces a permutation between edges and labels.

There's a secondary item v for each vertex; its color will be its label.

```
There's a secondary item +k for each vertex label; its color will be the vertex so labeled.
```

```
\langle \text{ Output the item-name line } 3 \rangle \equiv
